

DBMS day-4 assignments

Stored Procedure

1. Write a stored procedure that will accept the Employee Name and display the details of that Employee including the Department Name
2. Write a **function** that returns the Count of Employees who have joined between "01 Jan 80" and "01 Dec 81".
3. Write a stored procedure called CustomersWith60Installments(). This takes no argument, uses the Loan Accounts table and displays all customers with 60 installments
4. Write a stored procedure that accepts Sales person information as parameter and inserts this information into the Salespeople table.
5. Write a JDBC program to call a procedure fetch_SupplierInfo(custid) which should return all the details of the supplier for the customer whose cust-id is passed as an argument.
6. Write a **function** that will returns the total value of orders on a particular day. Pass the date as input and the function must return the total order value. So, if 5 orders were taken on 10/03/96, then find the total sum of all 5 orders amount

JDBC

Problem-1:

Redo the login application in collections. Accept username and password from user. Validate against a database table

Problem -2:

Refer to **problem #3** in Collections that used the Book class.

You already have the Book class.

You probably already have the BookManagerIntf that has the following methods:

- public void addBook(Book book) -> add a new book to table. If Book with that Book-id already exists, throw a BookAlreadyExistsException.
- public void deleteBook(int bookId) -> delete book with given id from table (use remove() method of Iterator). If book does not exist, throw a BookNotFoundException
- public Book[] displayAllBooks() -> fetch all books in Book table
- public Book getBookWithId(int bookId) -> **fetch** book with given id from table. If book does not exist, throw a BookNotFoundException
- public List<Book> getBooksByAuthor(String author) - fetch all books written by specified author
- public void incrPrice(int bookId, int amount) : **increment price of given book (bookid) with given amount and update the row in the table (extra method)**

Create a table called Book in the database which has columns that are same name as the Book class

Create a BookDao class that implements all methods of the interface. Use JDBC code to implement all the operations

Write a java class DBConn with a static method to obtain the database connection and another method to release the connection. Ensure you always get the connection wherever required throughout the application using this class only.

Create a class TestBookManager that has a main method. Create instance of BookDao and call all above operations on this TestBookManager object
